

With an aging and more active elderly population, acute traumatic brain injuries, in particular Acute Subdural Hematoma (SDH), are frequent. Management of these acutely ill patients remains a challenge. Should we aggressively treat all patients or are there any criteria in their medical history and presentation that can help us make these difficult decisions? We analyzed our Level I trauma database with the hope of answering these questions.

We retrospectively analyzed 109 consecutive patients 80 years and older who were admitted with acute SDH to our institution. Patients who were analyzed were registered in our department's trauma database from its creation in January 2000 through May 2012.

Mechanism of Injury	Non-survivors (%)	Survivors (%)
Fall from Standing	41.0	74.0
Motor Vehicle Accident	16.0	13.0
Fall from Height	20.0	5.0
Gunshot Wound	5.0	0.0
Fall from Bed	5.0	2.0
Fall from Sitting	13.0	4.0
Assault	0.0	2.0
Delayed fall	0.0	4.0

One hundred and nine patients (43.1% male, 56.8% female) were admitted with an acute subdural hematoma. Twenty seven patients died in the hospital (24.7%). Five were discharged to hospice, for an overall mortality of 32/109 (29.3%). Differences between surviving and non-surviving patients included SDH width on initial imaging (9.7 mm vs. 15.2 mm), GCS on presentation (13.28 vs 6.9), time to surgery (49.73 vs 31 hours), concurrent broken bone (25% vs 40%), and pupillary reaction in the emergency room (surviving patients: 54/62 briskly reactive, 6/62 sluggish, 2/62 nonreactive; vs. non-surviving patients: 12/25 nonreactive, 3/25 sluggish, 10/25 briskly reactive). Factors which did not differ between surviving and non-surviving patients included number of days spent in the ICU, percent receiving anticoagulation (53% vs 61%), and percent with the following comorbidities: hypertension, diabetes, cancer, stroke, or coronary artery disease.

**Primary Outcome in 109 patients:** - 75.2% survivors to home, rehab, or nursing facility  
- 24.8% non survivors

**Left Pupil Reactivity**

Category	Non-survivors	Survivors
Non-Reactive	50.0%	3.2%
Sluggish	8.3%	11.1%
Reactive	41.7%	85.7%

**Right Pupil Reactivity**

Category	Non-survivors	Survivors
Non-Reactive	45.8%	3.2%
Sluggish	12.5%	8.1%
Reactive	41.7%	88.7%

Profession	Men (%)	Women (%)
IT/IT	90.0%	88.0%
CAD	86.0%	55.1%
Consumer Business	51.1%	25.0%
Accounting/Finance	57.1%	53.0%
Accounting/IT	62.0%	67.0%
AF/IT	60.0%	22.4%
History of Civil	30.0%	27.2%
Defense	6.6%	28.6%
Career	22.6%	17.9%
Politics/Politics	4.0%	4.0%

	Non-survivors	Survivors	P value
Time to Surgery (hours, mean $\pm$ SD)	26.7 $\pm$ 40.8	42.4 $\pm$ 96.2	0.420

Procedure Type	Non-survivors (%)	Survivors (%)
None	50.0%	59.7%
Craniotomy	50.0%	29.0%
Burr hole	0.0%	11.3%

By the conclusion of this session, participants should be able to: 1) Define the severity of the injury of the elderly patients; 2) Discuss the different treatment options for acute subdural hematoma; 3) Evaluate the impact of complicating comorbidities; and 4) Integrate patient-specific factors to formulate an individualized treatment plan.

Pre-existing comorbidities should not deter treatment of elderly patients presenting with acute SDH. With 70.3% of patients being discharged to home, acute rehabilitation, or a skilled nursing facility with hope for meaningful recovery, it remains appropriate to offer aggressive medical and surgical intervention if it is consistent with the patient and their family's wishes.

Taussky P, Hidalgo ET, Landolt H, Fandino J. Age and salvageability: analysis of outcome of patients older than 65 years undergoing craniotomy for acute traumatic subdural hematoma. *World Neurosurg.* 2012 Sep-Oct;78(3-4):306-11.
